Revised paper (unmarked), submitted to Composite Structures
Abstract

Compared with triangular, square and Kagome honeycombs, hexagonal honeycombs have lower in-plane stiffness, which restricts their multifunctional applications. Focusing on this problem, in this paper, we analytically study the in-plane elastic and transport properties of a kind of hexagonal honeycombs, i.e., the multifunctional hierarchical honeycomb (MHH). The MHH structure is developed by replacing the solid cell walls of the original regular hexagonal honeycomb (ORHH) with three kinds of equal mass isotropic honeycomb sub-structures possessing hexagonal, triangular and Kagome lattices. Formulas to derive the effective in-plane elastic properties of the regular hexagonal honeycombs at all densities are developed for analyzing the MHH structure. Results show that the hexagonal sub-structure does not improve much the elastic properties of the MHH structure. However, the triangular and Kagome sub-structures result in a substantial improvement by 1 magnitude or even 3 orders of magnitude on the Young’s and shear moduli of the MHH structure, depending on the cell-wall thickness-to-length ratio of the ORHH. Besides, the effective in-plane conductivities (or dielectric constants) of the three different MHH structures are also studied. The presented theory could be used in designing new tailorable hierarchical honeycomb structures for multifunctional applications.

Keywords: In-plane effective moduli; In-plane effective conductivity (or dielectric constants); Original regular hexagonal honeycomb (ORHH); Multifunctional hierarchical honeycomb (MHH).
1. Introduction

Low-density cellular materials widely exist in nature and exhibit fascinating mechanical properties in the aspects of strength, stiffness, toughness, etc. [1-3]. As one kind of typical low density cellular solids, honeycombs, which are mainly used as cores of the light-weight sandwich panel structures [4-7], have been used in many diverse fields, such as aerospace and automotive industries. Apart from their peculiar low-density and mechanical properties, honeycombs also show other attractive functionalities, e.g., heat transfer, thermal protection, catalysis application and so on. In order to find optimal topologies for different multifunctional applications, varieties of prismatic honeycombs have been studied in recent years.

Regarding the multifunctionality of honeycomb materials, Lu [8] and Gu et al. [9] reported that regular hexagonal metal cells, comparing with triangular and square cells, provide the highest level of heat dissipation, as comparable to that of the open-cell metal foams. Combining the experimental and numerical methods, Wen et al. [10] revealed that the overall thermal performance of metal honeycomb structures are superior to other heat sink media, such as metal foams, lattice-frame materials, 3D Kagome structures and woven textile structures. Employing the topology optimization technique, Hyun and Torquato [11] showed that the effective conductivity of the regular hexagonal honeycomb is nearly approaching the Hashin-Shtrikman (H-S) upper bounds; while for triangular and Kagome honeycombs, both the in-plane effective moduli and conductivity are approaching the H-S upper bounds [12-13]. Besides, Evans et al. [14], Wadley et al. [15] and Wadley [16] reviewed the multifunctionalities and the fabrication technologies of the multifunctional periodic cellular metals with different topological structures. Hayes et al. [17] studied the mechanical and thermal properties of linear cellular alloys with square cells, and concluded that the mechanical and heat transfer characteristics of the honeycomb materials outperformed those of the open- and closed-cell metal foams with comparable relative density. Vaziri and collaborators focused on metallic sandwich panels with different kinds of cellular cores
such as hexagonal honeycombs [18], square honeycombs [19-23], open-cell rhombic dodecahedron cellular structures [24] and pyramidal truss cores [25-28], and explored some of their multifunctional applications, such as energy absorptions [27], sustaining shock loadings [19-21] and underwater impulsive loadings [22-23].

Regarding the mechanical properties of honeycomb materials, Wang and McDowell [29] investigated the in-plane stiffness and yield strength of different periodic metal honeycombs, and showed that the diamond, triangular and Kagome cells have superior in-plane mechanical properties to the hexagonal, rectangular and mixed square/triangular cells. Fleck and Qiu [30] analyzed the damage tolerance property of 2D elastic-brittle isotropic honeycombs and reported that Kagome cells have much higher fracture toughness than those of the hexagonal and triangular cells.

Another character related to honeycomb materials is the concept of hierarchy. Compared with their single length scale microstructure counterparts, structural hierarchy in natural materials can result in significantly higher stiffness or strength efficiencies (i.e. stiffness- or strength-to-weight ratios), and at the same time maintain their flaw-tolerance or energy-absorbing property [31-36]. Combining the low-weight property of cellular solids and the particular functions that natural hierarchical materials display, many researchers [37-44] have focused on the mechanical properties of the hierarchical cellular structures. Burgueno et al. [45] studied the hierarchical cellular designs for load-bearing bio-composite beams and plates. Kooistra et al. [46] investigated hierarchical corrugated core sandwich panels and revealed that second-order trusses could have much higher compressive and shear strengths than their equal-mass first-order counterparts when the relative densities are less than 5%. Fan et al. [47] studied two-dimensional cellular materials made up of sandwich struts and showed that the relevant mechanical properties of the materials were improved substantially by incorporating structural hierarchy. Inspired by diatom algae which contains nanoporous hierarchical silicified shells, Garcia et al. [48] revealed the toughening mechanism in the superductile wavy silica nanostructures by performing a series of molecular dynamics simulations. Taylor et al. [49] introduced the functionally graded hierarchical honeycombs by
performing a set of finite element analyses, and their results suggested that the elastic modulus of the functionally graded hierarchical honeycomb could be 1.75 times that of its equal-mass first-order hexagonal honeycomb if the structure is designed properly. Different from the topology of the common hierarchical honeycomb structures [37-38, 43, 49], Vaziri’s group recently [50] developed a new hierarchical honeycomb structure by replacing every three-edge joint of a regular hexagonal lattice with a smaller hexagon, and showed that the elastic moduli of the hierarchical honeycombs with one level and two levels can be 2.0 and 3.5 times stiffer than their equal-mass regular hexagonal honeycomb, respectively. And more, inspired by natural materials, Chen and Pugno [42-44] explored nanomechanics of 2D hierarchical honeycombs and 3D hierarchical foams.

In this paper, following the above works, we analytically study the in-plane elastic moduli and thermal conductivity of the multifunctional hierarchical honeycomb (MHH). The term “multifunctional” is here used to describe a material that has different peculiar functions activated simultaneously by the same concept of “hierarchy”. The MHH structure is formed by replacing the solid cell walls of an original regular hexagonal honeycomb (ORHH) with three different isotropic honeycomb sub-structures possessing hexagonal, triangular or Kagome lattices. First, we derive the analytical formulas of the effective elastic moduli of the regular hexagonal honeycombs for all densities. Then, the in-plane Young’s, shear and bulk moduli of the three kinds of MHH structures are calculated. Besides, the effective in-plane conductivities of the three kinds of MHH structures are formulated through the H-S upper bounds.

2. Effective in-plane elastic moduli of the regular hexagonal honeycombs for all densities

Hyun and Torquato [51] analytically studied the effective in-plane properties of the regular hexagonal honeycomb for all densities via the three-point approximations and expressed the effective Young’s modulus $E_c$ (Fig. 1b) as

$$\frac{E_c}{E_s} = \frac{\phi(2\zeta-1)(\zeta+\eta-1)}{3-2\phi-2(2-\phi)(1-\zeta)+(2-\zeta-\eta)\left[2\phi(1-\zeta)-1\right]}$$

(1)
in which $\phi$ is the relative density of the hexagonal honeycomb, $E_s$ is the Young’s modulus of the constituent solid, $\zeta$ and $\eta$ are the three-point parameters (Fig. 1a). The simulation data of the effective Young’s modulus $E_e$ [51] are also provided in Fig. 1b. It is apparent that for the high density case ($\phi \geq 0.5$), the three-point approximations method matches very well the simulation data, but for the lower densities it overestimates the results. In the very low density case, the overestimation is so large that the three-point approximations method is not suitable.

It is well-known that for the low-density regular hexagonal honeycombs, the Euler beam theory and the Timoshenko beam theory could be used to obtain very good analytical results for predicting their elastic parameters. Here, in order to get the analytical formulas for the in-plane elastic parameters of the regular hexagonal honeycomb at all densities, we apply the Euler beam theory and the Timoshenko beam theory to the entire range of the relative density and compare the results with the three-point approximations. Under the Euler beam theory, Torquato et al. [52] expressed the effective Young’s modulus $E_e$ as:

$$\frac{E_e}{E_s} = \frac{3}{2} \phi^3$$

(2)

On the other hand, Gibson and Ashby [3] studied the elastic properties of the low density honeycombs using the Timoshenko beam theory. For the regular hexagonal honeycombs, the effective Young’s modulus is given by:

$$\frac{E_e}{E_s} = \frac{4}{\sqrt{3}} \left(\frac{t}{l}\right)^{1/2} \frac{1}{1 + (5.4 + 1.5\nu_s) (t/l)^2}$$

(3)

in which $\nu_s$ is the Poisson’s ratio of the constituent solid and $t/l = \sqrt{3} \left(1 - \sqrt{1 - \phi}\right)$ is the cell wall thickness-to-length ratio.

For honeycombs at all densities, the comparisons between the Euler beam theory, Timoshenko beam theory, three-point approximations method and the simulation data are plotted in Fig.1b. We can see that when $\phi \leq 0.5$ the results calculated by the Euler beam theory matches very well the
simulation data, while the results are well predicted by the three-point approximations when \( \phi > 0.5 \). Therefore, the effective Young’s modulus of the regular hexagonal honeycombs for all densities can be expressed as:

\[
\frac{E_e}{E_s} = \begin{cases} 
\frac{3}{2} \phi & \phi \leq 0.5 \\
\frac{\phi(2\zeta - 1)(\zeta + \eta - 1)}{\left\{3 - 2\phi - 2(2 - \phi)(1 - \zeta) + (2 - \zeta - \eta)[2\phi(1 - \zeta) - 1]\right\}} & \phi > 0.5
\end{cases}
\]  

(4)

Besides, through the three-point approximations, Hyun and Torquato [51] also developed the expression for the effective in-plane bulk modulus \( k_e \) of the regular hexagonal honeycombs at all densities:

\[
k_e = \frac{G_e \phi (2\zeta - 1)}{k_s (1 - \phi) + G_s [1 + 2\phi(\zeta - 1)]} = \frac{G_e / k_s \phi (2\zeta - 1)}{(1 - \phi) + G_s / k_s [1 + 2\phi(\zeta - 1)]}
\]  

(5)

where \( k_s \) and \( G_s \) are the bulk and shear moduli of the constituent solid, respectively.

Because of the in-plane isotropic properties, \( k_s \), \( E_s \), \( k_e \), \( G_e \) and \( E_e \) satisfy the following relationships:

\[
k_s = \frac{E_s}{2(1 - \nu_s)}
\]  

(6)

\[
k_e = \frac{E_e}{2(1 - \nu_e)}
\]  

(7)

\[
G_e = \frac{E_e}{2(1 + \nu_e)}
\]  

(8)

in which \( G_e \) and \( \nu_e \) are the effective in-plane shear modulus and Poisson’s ratio of the hexagonal honeycombs, respectively. Defining \( E_e / E_s = A \) and \( k_e / k_s = B \), Eqs. (4-8) provide the formula for \( G_e \):

\[
\frac{G_e}{E_s} = \frac{AB}{4B - 2A(1 - \nu_s)}
\]  

(9)

Then, the effective Poisson’s ratio \( \nu_e \) of the regular hexagonal honeycombs can be derived through...
 dividing Eq. (6) by Eq. (7):

\[ \nu_e = 1 - \frac{A}{B}(1 - \nu_s) \] (10)

To verify the expressions of \( E_e, k_e \) and \( G_e \), Eq. (10) is depicted in Fig. 2 for the honeycombs at all densities with \( \nu_s = 1/3 \). Note that in the calculations, the three-point parameters \( \zeta \) and \( \eta \) are interpolated from Fig.1a and the relation \( G_e = E_e/[2(1 + \nu_s)] \) is used.

Fig. 2 shows excellent agreement with the existing results [3, 53], that is to say, the 2D effective Poisson’s ratio flows to a fixed point as the percolation threshold is reached. Here \( \nu_e \) tends to 1 for the extreme low densities and tends to the Poisson’s ratio of constituent solid \( \nu_s = 1/3 \) for the extreme high densities. This implies the validations of Eqs. (4), (5) and (9). It is worth to point out that different from the formula in Ref. [3], here the Poisson’s ratio is not a constant when the relative density is low.

3. MHH with isotropic hexagonal sub-structure

3.1 Basic theory

First of all, we consider the MHH with isotropic hexagonal lattice sub-structure (Fig. 3). Fig. 3a is an ORHH with the cell-wall thickness and length denoted by \( t_0 \) and \( l_0 \), respectively; Fig. 3b is an equal-mass MHH with the cell-wall thickness and length denoted by \( t_1 \) and \( l_0 \), respectively. We can see that the cell-wall lengths of the ORHH and the MHH are identical. In particular, one of the MHH cell walls in Fig. 3b is shown in Fig. 3c, and the cell-wall thickness and length for hexagonal cells are denoted by \( t_h \) and \( l_h \), respectively. The out-of-plane depth is a constant and identical for both structures.

The geometry of Fig. 3c implies:

\[ l_0 = nl_h + (n+1)(2l_0) = (3n+2)l_h \] (11)

where, \( n \) is the number of the solid hexagonal cell walls lying on the middle line of the MHH cell.
walls (e.g., in Fig. 3c, \( n=8 \)). Defining \( \lambda = l_h / l_0 \) as the hierarchical length ratio, rearranging Eq. (11) provides,

\[
\lambda = \frac{1}{3n + 2}
\]  

(12)

Then, defining \( N \) as the number of hexagonal cells away from the middle line of the MHH cell walls (e.g., in Fig. 3c, \( N=1 \)), and \( M \) the total number of half-thickness hexagonal cells in a MHH cell wall (see Fig. A in appendix A), the relationship between \( M \) and \( N \) can be expressed as:

\[
M = 2N(2n+1) + \frac{n}{3} - 4A_N
\]  

(13)

with \( A_N = [(2N+1)(N-1)+1]/6 \) (see Appendix A). After that, basing on the mass equivalence between cell walls of the MHH and the ORHH, we find

\[
t_h = \frac{1}{\lambda} \left( \frac{t_0^2}{2} - \frac{1}{2\sqrt{3}} \right)
\]  

(14)

Besides, a geometrical analysis on Fig. 3c provides \( N_{\text{max}} \), the upper bound of \( N \), and \( t_1 \), the thickness of the MHH cell walls:

\[
N_{\text{max}} = \lceil \frac{1}{2\lambda} \rceil = \lceil \frac{3n + 2}{2} \rceil
\]  

(15)

\[
t_1 = \begin{cases} 2N(\sqrt{3}t_h) + t_h & 1 \leq N \leq N_{\text{max}} - 1 \\ 2 \times \frac{\sqrt{3}}{2} t_0 & N = N_{\text{max}} \end{cases}
\]  

(16)

where, ‘\( \lceil \rceil \)’ is the floor function, which denotes the largest integer not greater than the term in the bracket. Then, rearranging Eq. (16) gives:

\[
t_h / t_0 = \begin{cases} \left( \frac{2\sqrt{3}N + t_h}{t_h} \right) \lambda & 1 \leq N \leq N_{\text{max}} - 1 \\ \sqrt{3} & N = N_{\text{max}} \end{cases}
\]  

(17)
On the other hand, with respect to Eq. (14), the relation
\[ 1 - 2 \sqrt[3]{3} \lambda^2 M \left( \frac{t_0}{l_0} \right)^3 \left( \frac{t_0}{l_0} \right)^3 \geq 0 \]
should be satisfied. Considering Eqs. (12) and (13), this relation provides \( N_{\text{min}} \), the lower bound of \( N \):

\[
N_{\text{min}} = \left[ \frac{3n + 2 - \sqrt{3n^2 + 2}}{2} \right]
\]

where \( 'ce[ \ ]' \) is the ceiling function, which denotes the smallest integer not less than the term in the bracket. Note that Eq. (18) may give \( N_{\text{min}} = 0 \), in this case \( N_{\text{min}} = 1 \).

Defining the in-plane Young’s, shear and bulk moduli of the ORHH as \( E_o, G_o \) and \( k_o \), then, from Eqs. (4), (5) and (9), we find:

\[
\frac{E_o}{E_s} = \frac{3}{2} \phi_o^3 \quad \phi_o \leq 0.5
\]

\[
\frac{G_o}{G_s} = \frac{\phi_o (2 \zeta_o - 1)(\zeta_o + \eta_o - 1)}{3 - 2\phi_o - 2(2 - \phi_o)(1 - \zeta_o) + (2 - \zeta_o - \eta_o)[2\phi_o(1 - \zeta_o) - 1]} \quad \phi_o > 0.5
\]

\[
\frac{k_o}{k_s} = B_o = \frac{G_s/k_s \phi_o (2 \zeta_o - 1)}{(1 - \phi_o) + G_s/k_s [1 + 2\phi_o(\zeta_o - 1)]}
\]

\[
\frac{G_o}{E_s} = \frac{A_o B_o}{4B_o - 2A_o (1 - \nu_s)}
\]

where,

\[
\phi_o = \frac{2}{3} \left( \frac{t_0}{l_0} \right)^2 \quad \left( \frac{t_0}{l_0} \leq \sqrt{3} \right)
\]

is the relative density of the ORHH, and \( \zeta_o \) and \( \eta_o \), interpolated from Fig. 1a, are the corresponding three-point parameters.

Besides, Hyun and Torquato [11, 51] showed that the effective thermal conductivity of the regular hexagonal honeycomb nearly approaches the H-S upper bounds. Thus, defining the thermal
conductivities of the ORHH and the constituent solid as $\sigma_O$ and $\sigma_s$, we approximately obtain:

$$\frac{\sigma_O}{\sigma_s} = \frac{\phi_O}{2 - \phi_O}$$  \hspace{1cm} (23)

Note that due to the mathematical analogy, results for the effective thermal conductivity translate immediately into the equivalent results for the effective dielectric constant, electrical conductivity and magnetic permeability.

Similarly, defining the in-plane Young’s, shear and bulk moduli and thermal conductivity of the hexagonal sub-structure as $E_h$, $G_h$, $k_h$ and $\sigma_h$, we obtain:

$$\frac{E_h}{E_s} = A_h = \begin{cases} \frac{3}{2} \phi_h & \phi_h \leq 0.5 \\ \phi_h \frac{(2\zeta_h - 1)(\zeta_h + \eta_h - 1)}{\left\{3 - 2\phi_h - 2(2 - \phi_h)(1 - \zeta_h) + (2 - \zeta_h - \eta_h)\left[2\phi_h (1 - \zeta_h) - 1\right]\right\}} & \phi_h > 0.5 \end{cases}$$  \hspace{1cm} (24)

$$\frac{k_h}{k_s} = B_h = \frac{G_s/k_s \phi_h (2\zeta_h - 1)}{(1 - \phi_h) + G_s/k_s \left[1 + 2\phi_h (\zeta_h - 1)\right]}$$  \hspace{1cm} (25)

$$\frac{G_h}{E_s} = \frac{A_h B_h}{4B_h - 2A_h (1 - \nu_h)}$$  \hspace{1cm} (26)

$$\frac{\sigma_h}{\sigma_s} = \frac{\phi_h}{2 - \phi_h}$$  \hspace{1cm} (27)

where,

$$\phi_h = \frac{2}{\sqrt{3}} l_h \left(\frac{L_h}{l_h}\right)^3 \quad \left(l_h \leq \sqrt{3}\right)$$  \hspace{1cm} (28)

is the relative density of the hexagonal sub-structure, and $\zeta_h$ and $\eta_h$, interpolated from Fig. 1a, are the corresponding three-point parameters. Denoting the effective Poisson’s ratio of the hexagonal sub-structure by $\nu_h$, the relation $G_h = E_h / [2(1 + \nu_h)]$ is satisfied. Then, combining Eqs. (24) and (26) gives,

$$\nu_h = 1 - \frac{A_h}{B_h} (1 - \nu_s)$$  \hspace{1cm} (29)
Thus,

$$\frac{G_{h}}{k_{h}} = \frac{E_{h}}{E_{h}} = \frac{\sqrt{\frac{2}{2+1}}}{2(1-v_{h})} = \frac{1-v_{h}}{1+v_{h}} = \frac{A_{h}}{2B_{h} - A_{h}(1-v_{h})}$$

(30)

At the same time, by treating the hexagonal sub-structure as a continuum and defining the in-plane Young’s, shear and bulk moduli and thermal conductivity of the MHH as $E_{M}$, $G_{M}$, $k_{M}$ and $\sigma_{M}$, it is easy to obtain:

$$\frac{E_{M}}{E_{h}} = A_{M} = \begin{cases} \frac{3}{2} \phi_{M} & \phi_{M} \leq 0.5 \\ \frac{\phi_{M} (2 \zeta_{M} - 1)(\zeta_{M} + \eta_{M} - 1)}{3 - 2\phi_{M} - 2(2 - \phi_{M})(1 - \zeta_{M}) + (2 - \zeta_{M} - \eta_{M})[2\phi_{M} (1 - \zeta_{M}) - 1]} & \phi_{M} > 0.5 \end{cases}$$

(31)

$$\frac{k_{M}}{k_{h}} = B_{M} = \frac{G_{h}/k_{h} \phi_{M} (2 \zeta_{M} - 1)}{(1 - \phi_{M}) + G_{h}/k_{h} [1 + 2\phi_{M} (\zeta_{M} - 1)]}$$

(32)

$$\frac{G_{M}}{E_{h}} = \frac{A_{M}B_{M}}{4B_{M} - 2A_{M}(1-v_{h})}$$

(33)

$$\frac{\sigma_{M}}{\sigma_{h}} = \frac{\phi_{M}}{2 - \phi_{M}}$$

(34)

where,

$$\phi_{M} = \frac{2}{\sqrt{3}} \frac{t_{1}}{t_{0}} - \frac{1}{3} \left( \frac{t_{1}}{t_{0}} \right)^{2} \left\{ \frac{t_{1}}{t_{0}} \leq \sqrt{3} \right\}$$

(35)

and $\zeta_{M}$ and $\eta_{M}$, interpolated from Fig. 1a, are the three-point parameters corresponding to $\phi_{M}$.

Combining Eqs. (19), (24) and (31) gives the relative Young’s modulus $E_{M}/E_{O}$:

$$\frac{E_{M}}{E_{O}} = \frac{A_{M}A_{b}}{A_{O}}$$

(36)

Similarly, from Eqs. (20), (25) and (32), we can get the relative in-plane bulk modulus $k_{M}/k_{O}$:

$$\frac{k_{M}}{k_{O}} = \frac{B_{M}B_{h}}{B_{O}}$$

(37)

And from Eqs. (21), (24) and (33), we obtain the relative shear modulus $G_{M}/G_{O}$:
Finally, from Eqs. (23), (27) and (34), we get the relative thermal conductivity $\frac{\sigma_M}{\sigma_O}$:

$$\frac{\sigma_M}{\sigma_O} = \frac{\phi_M\phi_h (2 - \phi_O)}{\phi_O (2 - \phi_M)(2 - \phi_h)}$$  \hspace{1cm} (39)

### 3.2 Effect of $N$ on the relative elastic moduli and thermal conductivity of the MHH with hexagonal sub-structure

To investigate the influence of $N$ on the relative elastic parameters $\frac{E_M}{E_O}$, $\frac{G_M}{G_O}$, $\frac{k_M}{k_O}$ and the relative thermal conductivity $\frac{\sigma_M}{\sigma_O}$, here, we discuss the following examples with parameters $n = 16$, $\lambda = 1/(3n + 2) = 0.02$ and $t_0/l_0 = 0.01$, 0.05, 0.1, 0.2 and 0.3. Then, we can find $N_{\text{max}} = 25$ through Eq. (15), and $N_{\text{min}}$ for each $t_0/l_0$ through Eq. (18). The results of the relative elastic parameters $\frac{E_M}{E_O}$ and $\frac{G_M}{G_O}$, $\frac{k_M}{k_O}$ and the relative thermal conductivity $\frac{\sigma_M}{\sigma_O}$ versus $N$ are reported in Figs. 4-6, respectively.

From Figs. 4a and 4b, we can see that for all the $t_0/l_0$ ratios considered, the optimal $\frac{E_M}{E_O}$ and $\frac{G_M}{G_O}$, which vary between 1 and 2, exist as $N$ increases. Note that the optimal $\frac{E_M}{E_O}$ and $\frac{G_M}{G_O}$ may do not correspond to the same $N$. The reason is that $E_O/E_s$ and $E_M/E_h$ are independent of the Poisson’s ratios $\nu_s$ and $\nu_h$ but $G_O/G_s$ and $G_M/G_h$ are dependent on them [51].

Figs. 5 and 6 show that the relative bulk modulus $\frac{k_M}{k_O}$ and the relative thermal conductivity $\frac{\sigma_M}{\sigma_O}$ increase with the increase of $t_0/l_0$, but they are generally less than 1 for all the $t_0/l_0$ ratios considered. This means that the effective bulk modulus and thermal conductivity of the MHH with regular hexagonal sub-structure are smaller than those of the ORHH structure. Of particular interest, there is an optimal value for the thermal conductivity, and this could be used to design low heat conductivity materials with an optimal topology.
3.3 The effects of $t_0/l_0$ – the cell-wall thickness-to-length ratio of the ORHH

To investigate the effects of the cell-wall thickness-to-length ratio $t_0/l_0$ of the ORHH on the relative elastic parameters and thermal conductivity of the MHH structure, again, we use the examples given in Section 3.2. We maintain $n = 16$, $\lambda = 0.02$ but change $t_0/l_0$ from 0.01 to 0.5 with the incremental step of 0.01. In fact, under the same $N$, the value of $G_M/G_O$ is in general weakly larger than $E_M/E_O$ (Fig. 4), so here we only consider the relative Young’s modulus $E_M/E_O$ against $t_0/l_0$. At the same time, $\sigma_M/\sigma_O$ and $k_M/k_O$ generally are smaller than 1 for all $t_0/l_0$ as those shown in Figs. 5 and 6, thus, the discussion will not be treated in this section.

Finally, the relationship between the maximum $E_M/E_O$ and $t_0/l_0$ is reported in Fig. 7. We can see that the maximum $E_M/E_O$ increases before $t_0/l_0$ reaches 0.07 but after that it decreases. That is to say, the optimal $E_M/E_O$ of the MHH with hexagonal sub-structure exists at $t_0/l_0 = 0.07$, of which the value approximately equals to 2. This result is comparable to the finite element result given by Taylor et al. [49].

4. MHH with triangular sub-structure

4.1 Basic theory

In this section, we substitute the ORHH cell walls with the equal-mass isotropic triangular sub-structure, see Fig. 8. As defined in Section 3, the hierarchical length ratio is expressed as

$$\lambda = \frac{l'}{t_0} = \frac{1}{n} \quad (n \geq 1)$$

(40)

where, $n$ is the number of solid triangular lattice cell walls lying on the middle line of the MHH cell walls. From Fig. 8c, according to the equal-mass principle, we can find

$$t_0 / l_0 = \frac{1}{2\sqrt{3}} t_0^2 = 3 \times \frac{1}{2} \left( t_l - \frac{\sqrt{3}}{2} t_i^2 \right) M,$$

which gives
\[
\frac{t_i}{t} = \frac{1}{\sqrt{3}} \left[ 1 - \sqrt{1 - \frac{4\sqrt{3}}{3\lambda^2 M} t_0 \left( 1 - \frac{1}{2\sqrt{3}} t_0 \right)} \right]
\]  

(41)

where, \( M \) is the total number of half thickness triangular lattice cells in a MHH cell wall and it has the following relationship with \( n \) and \( N \) (see Appendix B):

\[
M = 2N(2n-N) + \frac{2}{3}(n-N) \quad (1 \leq N \leq n)
\]

(42)

in which \( N \) is the number of triangular lattice cells away from the middle line of the MHH cell walls. Similar to that in Section 3, a geometrical analysis on Fig. 8c provides \( N_{\text{max}} \), the upper bound of \( N \), and \( t_i \), the thickness of the MHH cell walls:

\[
N_{\text{max}} = n
\]

(43)

\[
t_i = \begin{cases} 
2N\left( \frac{\sqrt{3}}{2} t_i \right) + t_i & 1 \leq N \leq N_{\text{max}} - 1 \\
2\times \frac{\sqrt{3}}{2} t_0 & N = N_{\text{max}}
\end{cases}
\]

(44)

Then, rearranging Eq. (44) gives,

\[
t_i = \begin{cases} 
\left( \frac{3N + t_i}{t_i} \right)^{\frac{1}{3}} & 1 \leq N \leq N_{\text{max}} - 1 \\
\sqrt{3} & N = N_{\text{max}}
\end{cases}
\]

(45)

On the other hand, with respect to Eq. (41), the relation

\[1 - 4\sqrt{3}/(3\lambda^2 M) t_0/\lambda_i \left[ 1 - 1/\left( 2\sqrt{3} t_0/\lambda_i \right) \right] \geq 0 \]

should be satisfied. In conjunction with Eqs. (40) and (42), this relation gives \( N_{\text{min}} \), the lower bound of \( N \):

\[
N_{\text{min}} = \frac{6n - 1 - \sqrt{(6n-1)^2 - 12n \left[ 2\sqrt{3} n t_0 \left( 1 - \frac{1}{2\sqrt{3}} t_0 \right) \right]}}{6}
\]

(46)

Note that Eq. (46) may give \( N_{\text{min}} = 0 \), in this case \( N_{\text{min}} = 1 \).
Like the discussion in Section 3, we would like to analyze the effective elastic moduli and thermal conductivity of the triangular lattice sub-structure. As already mentioned in the introduction, Hyun and Torquato [11] showed that for triangular and Kagome honeycombs, both the in-plane effective moduli and conductivity (or dielectric constant) are approaching the H-S upper bounds [12-13]. So, we approximately use the H-S upper bounds to calculate the effective elastic moduli and thermal conductivity of the triangular lattice sub-structure. Defining the in-plane Young’s, shear and bulk moduli and thermal conductivity of the triangular sub-structure as $E_t, G_t, k_t$ and $\sigma_t$, we obtain:

\[
\frac{E_t}{E_s} = A_t = \frac{\phi_t}{3 - 2\phi_t} \quad (47)
\]

\[
\frac{k_t}{k_s} = B_t = \frac{\phi_t G_s/k_s}{1 - \phi_t + G_t/k_s} \quad (48)
\]

\[
\frac{G_t}{E_s} = C_t = \frac{1}{2(1 + v_t)} \left( \frac{\phi_t}{1 - \phi_t + 2G_t/k_s} + 1 \right) \quad (49)
\]

\[
\frac{\sigma_t}{\sigma_s} = \frac{\phi_t}{2 - \phi_t} \quad (50)
\]

where,

\[
\phi_t = 2\sqrt{3} \frac{l_t}{l_s} - 3 \left( \frac{l_t}{l_s} \right)^2 \left( 1 \leq \frac{l_t}{l_s} \leq \frac{1}{\sqrt{3}} \right) \quad (51)
\]

is the relative density of the triangular sub-structure. Denoting the effective Poisson’s ratio of the triangular sub-structure by $v_t$, the relation $G_t = E_t / [2(1 + v_t)]$ holds. Then, combining Eqs. (47) and (49) gives,

\[
v_t = \frac{1}{2} A_t - 1 \quad (52)
\]

Thus,

\[
\frac{G_t}{k_t} = \frac{E_t / \left[ 2(1 + v_t) \right]}{E_t / \left[ 2(1 - v_t) \right]} = \frac{1 - v_t}{1 + v_t} = \frac{4C_t}{A_t} - 1 \quad (53)
\]
At the same time, by treating the triangular sub-structure as a continuum and defining the in-plane Young’s, shear and bulk moduli and thermal conductivity of the MHH with triangular sub-structure as \( E_M, G_M, k_M \) and \( \sigma_M \), we have:

\[
\frac{E_M}{E_o} = A_M = \begin{cases} 
\frac{3}{2} \frac{\phi_M}{J_2} & \phi_M \leq 0.5 \\
\frac{\phi_M}{J_2} & 0.5 < \phi_M < 1 \\
\frac{2}{J_2} (2 - \phi_M) & \phi_M \geq 1
\end{cases}
\]

(54)

\[
k_M = B_M = \frac{G_i/k_i \phi_M (2 \zeta_M - 1)}{(1 - \phi_M) + G_i/k_i [1 + 2 \phi_M (\zeta_M - 1)]}
\]

(55)

\[
\frac{G_M}{E_i} = \frac{1}{4B_M - 2A_M (1 - \nu)}
\]

(56)

\[
\frac{\sigma_M}{\sigma_i} = \frac{\phi_M}{2 - \phi_M}
\]

(57)

where,

\[
\phi_M = \frac{2}{\sqrt{3}} \frac{t_i}{l_0} - \frac{1}{3} \left( \frac{t_i}{l_0} \right)^2 \quad \left( \frac{t_i}{l_0} \leq \sqrt{3} \right)
\]

(58)

and \( \zeta_M \) and \( \eta_M \), interpolated from Fig. 1a, are the three-point parameters corresponding to \( \phi_M \).

Combining Eqs. (19), (47) and (54) gives the relative Young’s modulus \( E_M/E_o \):

\[
\frac{E_M}{E_o} = \frac{A_M A_i}{A_o}
\]

(59)

Similarly, from Eqs. (20), (48) and (55), we can find the relative bulk modulus \( k_M/k_o \):

\[
\frac{k_M}{k_o} = \frac{B_M B_i}{B_o}
\]

(60)

And from Eqs. (21), (47) and (56), we obtain the relative shear modulus \( G_M/G_o \):

\[
\frac{G_M}{G_o} = \frac{A_M B_M A_i}{2B_o - A_o (1 - \nu)} \frac{2B_o - A_o (1 - \nu)}{A_o B_o}
\]

(61)

Finally, from Eqs. (23), (50) and (57), the relative thermal conductivity \( \sigma_M/\sigma_o \) is derived:
\[
\frac{\sigma_M}{\sigma_o} = \frac{\phi_o \phi_l (2-\phi_o)}{\phi_o (2-\phi_m)(2-\phi_l)}
\]  

(62)

4.2 Effects of N on the relative elastic moduli and thermal conductivity of the MHH with triangular sub-structure

As discussed in Section 3, the influence of N on the effective elastic moduli and thermal conductivity of the MHH with triangular sub-structure are studied, here we consider other examples with parameters \( n = 20, \lambda = 1/n = 0.05, t_0/l_0 = 0.01, 0.05, 0.1, 0.2 \) and 0.3. Then, we immediately obtain \( N_{\text{max}} = 20 \) by Eq. (23) and the lower bound \( N_{\text{min}} \) for each \( t_0/l_0 \) by Eq. (46). The results of the relative elastic moduli \( E_M/E_o, G_M/G_o, k_M/k_o \) and the relative thermal conductivity \( \sigma_M/\sigma_o \) versus \( N \) are reported in Figs. 9-12, respectively.

From Figs. 9 and 10, we can also see that the relative Young’s modulus \( E_M/E_o \) and the effective shear modulus \( G_M/G_o \) increase with the increase of \( N \), and the thickness-to-length ratio \( t_0/l_0 \) has a strong influence on them. With respect to its equal-mass ORHH, the enhancements of the relative Young’s and shear moduli of the MHH with triangular sub-structure can be 1 order (Figs. 9c and 10c) or even 3 orders of magnitude (Figs. 9a and 10a). Although the enhancement on Young’s modulus of the MHH with triangular sub-structure decreases with the increase of \( t_0/l_0 \), for a relatively small \( t_0/l_0 \) (less than 0.3), its stiffening effect (Figs. 9 and 10) by the triangular sub-structure is much larger than that of the hexagonal sub-structure (Figs. 4a, b).

The relative bulk modulus \( k_M/k_o \) and the relative thermal conductivity \( \sigma_M/\sigma_o \) shown in Figs. 11 and 12 have the same varying trends with those of the MHH with hexagonal sub-structure reported in Section 3.2. The discussion is the same as before.

5. MHH with isotropic Kagome sub-structure

5.1 Basic theory

Kagome honeycomb has been revealed to have pronounced higher fracture toughness [30] and
better thermal-mechanical performance than the triangular honeycombs [54]. Therefore, in this section, we will consider the third topology of the MHH, namely, substituting the ORHH cell walls with their equal-mass Kagome sub-structure (Fig. 13), and study its effective elastic moduli and thermal conductivity. In this case, the hierarchical length ratio is expressed as:

$$\lambda = \frac{l_k}{l_0} = \frac{1}{n} \quad n = 4, 6, 8, 10 \ldots$$  

where, $l_k$ is the side length of triangles in Kagome cells and $n$ is the number of sides of the effective triangles on the middle line of the MHH cell walls. As discussed before, here, the equal-mass principle provides $t_o l_0 - \frac{1}{2\sqrt{3}} t_0^2 = 3\times \left( t_k l_k - \frac{\sqrt{3}}{2} t_k^2 \right) M$, and $t_k l_k l_0$ is derived as:

$$\frac{t_k}{l_k} = \frac{1}{\sqrt{3}} \left[ 1 - \sqrt{1 - \frac{2\sqrt{3}}{3\lambda^2 M l_0^2} \left( 1 - \frac{1}{2\sqrt{3}} \frac{l_0}{l_k} \right) } \right]$$  

$$\left( 64 \right)$$

where, $M$ is the total number of triangles in a MHH cell wall, and it is expressed with $n$ and $N$ as (see Appendix C):

$$M = 2N(n - N) \quad 1 \leq N \leq \frac{n}{2}$$  

$$\left( 65 \right)$$

in which $N$ is the number of the Kagome representative cells (e.g., in Fig. 13c, $N = 1$) away from the middle line of the MHH cell walls. Similar to that in Sections 3 and 4, a geometrical analysis on Fig. 13c provides $N_{\text{max}}$, the upper bound of $N$, and $t_1$, the thickness of the MHH cell walls:

$$N_{\text{max}} = \frac{n}{2}$$  

$$\left( 66 \right)$$

$$t_1 = \begin{cases} 
2N\left( \sqrt{3} l_k \right) + 2t_k & 1 \leq N \leq N_{\text{max}} - 1 \\
2\times \frac{\sqrt{3}}{2} l_o & N = N_{\text{max}} 
\end{cases}$$  

$$\left( 67 \right)$$

Then, rearranging Eq. (67) gives
\[
\frac{t_k}{l_0} = \begin{cases}
2 \left( \sqrt{3}N + \frac{t_k}{l_k} \right) & \text{if } 1 \leq N \leq N_{\text{max}} - 1 \\
\sqrt{3} & \text{if } N = N_{\text{max}}
\end{cases}
\] (68)

On the other hand, with respect to Eq. (64), the relation
\[1 - 2\sqrt{3}/(3\lambda^2M) \frac{t_0}{l_0} \geq 0\]
holds. In conjunction with Eqs. (63) and (65), this relation gives \(N_{\text{min}}\), the lower bound of \(N\):
\[
N_{\text{min}} = \left[ n - n \sqrt{1 - \frac{4\sqrt{3}}{3} \frac{t_0}{l_0} \left( 1 - \frac{1}{2\sqrt{3}} \frac{t_0}{l_0} \right)} \right] / 2
\] (69)

Also, it should be noted that Eq. (69) may give \(N_{\text{min}} = 0\), for this case \(N_{\text{min}} = 1\).

Here, we again approximately use the H-S upper bounds to analyze the effective elastic moduli and thermal conductivity of the Kagome lattice sub-structure. Defining the in-plane Young’s, shear and bulk moduli and thermal conductivity of the Kagome sub-structure as \(E_k, G_k, k_k\) and \(\sigma_k\), we obtain:
\[
\frac{E_k}{E_s} = A_k = \frac{\phi_k}{3 \phi_k - 1}
\] (70)

\[
\frac{k_k}{k_s} = B_k = \frac{\phi_k G_s / k_s}{1 - \phi_k + G_s / k_s}
\] (71)

\[
\frac{G_k}{E_s} = C_k = \frac{1}{2(1 + \nu_s)(1 - \phi_k)(1 + 2G_s / k_s) + 1}
\] (72)

\[
\frac{\sigma_k}{\sigma_s} = \frac{\phi_k}{2 - \phi_k}
\] (73)

where,
\[
\phi_k = \sqrt{3} \frac{t_k}{l_k} = \left( \frac{t_k}{l_k} \right)^2 \left( \frac{t_k}{l_k} \leq \frac{1}{\sqrt{3}} \right)
\] (74)

is the relative density of the Kagome sub-structure. Denoting the effective Poisson’s ratio of the
Kagome sub-structure by $\nu_k$, employing $G_k = E_k / \left[2(1+\nu_k)\right]$ and combining Eqs. (70) and (72) give

$$\nu_k = \frac{1}{2} \frac{A_k}{C_k} - 1$$

Thus,

$$\frac{G_k}{k_k} = \frac{E_k / \left[2(1+\nu_k)\right]}{E_k / \left[2(1-\nu_k)\right]} = \frac{1-\nu_k}{1+\nu_k} = 4 \frac{C_k}{A_k} - 1$$

Again, by treating the Kagome sub-structure as a continuum and defining the in-plane Young’s, shear and bulk moduli and thermal conductivity of the MHH with Kagome sub-structure as $E_M, G_M, k_M$ and $\sigma_M$, we have:

$$E_M/E_k = A_M = \begin{cases} 
\frac{3}{2} \phi_M^3 & \phi_M \leq 0.5 \\
\frac{\phi_M (2\zeta_M - 1)(\zeta_M + \eta_M - 1)}{\left[3 - 2\phi_M - 2(2 - \phi_M)(1 - \zeta_M) + (2 - \zeta_M - \eta_M)[2\phi_M (1 - \zeta_M) - 1]\right]} & \phi_M > 0.5
\end{cases}$$

$$k_M/k_k = B_M = \frac{G_k}{k_k} \frac{\phi_M (2\zeta_M - 1)}{(1 - \phi_M) + G_k/k_k \left[1 + 2\phi_M (\zeta_M - 1)\right]}$$

$$G_M/E_k = \frac{A_M B_M}{4B_M - 2A_M (1-\nu_k)}$$

$$\frac{\sigma_M}{\sigma_k} = \frac{\phi_M}{2 - \phi_M}$$

where,

$$\phi_M = \frac{2}{\sqrt{3}l_0} - \frac{1}{3} \left(\frac{t_1}{l_0}\right)^2 \left(\frac{t_1}{l_0} \leq \sqrt{3}\right)$$

and $\zeta_M$ and $\eta_M$ interpolated from Fig. 1a are the three-point parameters corresponding to $\phi_M$.

Combining Eqs. (19), (70) and (77) gives the relative Young’s modulus $E_M/E_O$:

$$\frac{E_M}{E_O} = \frac{A_M A_k}{A_O}$$

Similarly, from Eqs. (20), (71) and (78) we can get the relative bulk modulus $k_M/k_O$:
\[ \frac{k_M}{k_O} = \frac{B_M B_k}{B_O} \]  

(83)

And from Eqs. (21), (70) and (79) we obtain the relative shear modulus \( G_M / G_O \):

\[ \frac{G_M}{G_O} = \frac{A_M B_M A_k}{2B_M - A_M (1 - \nu_k)} \frac{2B_O - A_O (1 - \nu)}{A_O B_O} \]  

(84)

Finally, from Eqs. (23), (50) and (57), we find the relative thermal conductivity \( \sigma_M / \sigma_O \):

\[ \frac{\sigma_M}{\sigma_O} = \frac{\phi_M \phi_k (2 - \phi_O)}{\phi_O (2 - \phi_M)(2 - \phi_k)} \]  

(85)

### 5.2 Effects of \( n \) on the relative elastic moduli and thermal conductivity of the MHH with Kagome sub-structure

In this section, we consider the examples with parameters \( n = 20, \lambda = 1/n = 0.05, t_o/l_o = 0.01, 0.05, 0.1, 0.2 \) and 0.3. Then, Eq. (66) provides \( N_{\max} = 10 \) and Eq. (69) the lower bound \( N_{\min} \) for each \( t_o/l_o \). The results of the relative elastic moduli \( E_M / E_O, G_M / G_O, k_M / k_O \) and the relative thermal conductivity \( \sigma_M / \sigma_O \) versus \( N \) are shown in Figs. 14-17, respectively.

Comparing Figs. 14 and 15 with Figs. 9 and 10, we can see that the Young’s and shear moduli of the MHH with Kagome sub-structure are similar to those of the MHH with triangular sub-structure, so the discussion is the same as before.

However, it is worth to say that, different from the MHH with hexagonal and triangular sub-structures, the relative bulk modulus \( k_M / k_O \) and the relative thermal conductivity \( \sigma_M / \sigma_O \) of the MHH with Kagome sub-structure become larger than 1 with the increase of \( t_o / l_o \) (Figs. 16 and 17). This is to say, when \( t_o / l_o \) is large enough, the effective bulk modulus and thermal conductivity of the MHH with Kagome sub-structure could be greater than those of the ORHH structures.

### 6. Comparisons of hexagonal, triangular and Kagome sub-structures

Comparing the examples discussed in Sections 3 to 5, it is apparent that for the same ORHH,
the in-plane stiffness enhancements of the MHH with triangular and Kagome sub-structures could be much greater than that with the hexagonal sub-structure. To illustrate this point clearly, one more example with the parameters $t_0/l_0 = 0.1$ and $\lambda = 1/20$ is analyzed, and the result is plotted in Fig. 18, in which the relative Young’s modulus $E_m/E_o$ against $N$ for the MHH with the above three sub-structures are depicted. Interestingly, we find that the relative Young’s moduli of the MHH with triangular and Kagome sub-structures increase as $N$ increases, but it is inverse for the MHH with hexagonal sub-structure. And more, the Young’s modulus of the MHH with Kagome sub-structure is improved most with respect to the ORHH.

For the comparisons on bulk modulus and thermal conductivity of the three MHHs, the parameters $t_0/l_0 = 0.3$ and $\lambda = 1/20$ are employed, and the results are depicted in Figs. 19 and 20. From the two figures, we can say that the MHH with Kagome sub-structure is the optimal structure to design the elastic moduli and transport properties of the multifunctional regular hexagonal honeycomb.

7. Conclusions

In this paper, we have studied the in-plane elastic and transport properties of the MHH, which is formed by replacing the ORHH solid cell walls with three types of equal-mass isotropic honeycomb sub-structures. The analytical results show that with the hexagonal sub-structure it is difficult to greatly increase the Young’s and shear moduli of the MHH. Different from the hexagonal sub-structure, triangular and Kagome sub-structures share a similar improvement on the MHH’s Young’s and shear moduli, and the improvement is substantial, from 1 order to 3 orders of magnitude depending on the cell-wall thickness-to-length ratio $t_0/l_0$ of the ORHH. At the same time, if $t_0/l_0$ is large enough, the effective bulk modulus and transport ability of the MHH with Kagome sub-structure can be larger than those of the ORHH structure. These interesting results show a possibility to design hierarchical honeycombs for multifunctional applications, e.g., the metal MHH can be used as the core of light weight sandwich panels in electronic packages and
airborne devices, where both the structural and thermal characteristics are desirable.

**Appendix A: MHH cell wall with hexagonal sub-structures**

Fig. A.1 shows the representative cell walls of the MHH with regular hexagonal sub-structures shown in Fig. 3b. The mass of the sub-structure is distributed uniformly among the half-thickness hexagonal sub-structure cells within the blue hexagon.

From Fig. A.1 we can see that the number of the half-thickness hexagonal sub-structure cells $M$ can be determined by $n$ and $N$ as the following form:

$$M = 2N \left[ n + (n+1) \right] + \frac{1}{6} (2n) - 4A_N = 2N(2n+1) + \frac{n}{3} - 4A_N$$  \hspace{1cm} (A.1)

in which $A_1 = 1/6$ and $A_2 = 1$.

Here, $A_N$ depends on $N$, we find it generally expressed as:

$$A_N = \frac{(2N+1)(N-1)+1}{6} \quad (N \geq 1)$$  \hspace{1cm} (A.2)

**Appendix B: MHH cell wall with triangular sub-structures**

Fig. B.1 schematically shows the cell walls of the MHH with triangular sub-structures (Fig. 8b). The hierarchical length ratio is $\lambda = 1/n$. $M$ is the total number of the half-thickness triangular cells in one sub-structure cell wall. It is easy to get the following relation between $M$, $N$ and $n$:

$N=1$: $M = 2(2n \times 1 - 1) + \frac{2}{3}(n-1)$

$N=2$: $M = 2(2n \times 2 - 1 - 1 - 2) + \frac{2}{3}(n-2)$  \hspace{1cm} (B.1)

$N=3$: $M = 2(2n \times 3 - 1 - 1 - 2 - 2 - 3) + \frac{2}{3}(n-3)$

Then, by inductive method, we find:

$$M = 2(2n \times N - B_N) + \frac{2}{3}(n - N) \quad 1 \leq N \leq n$$  \hspace{1cm} (B.2)

with
\[ B_N = N^2 \]  

(Substituting Eq. (B.3) into Eq. (B.2) gives:

\[ M = 2N(2n - N) + \frac{2}{3}(n - N) \quad (1 \leq N \leq n) \]  

(Appendix C: MHH cell wall with Kagome sub-structures)

Fig. C.1 schematically shows the cell walls of the MHH with Kagome sub-structures. The hierarchical length ratio is \( \lambda = \frac{1}{2} \). \( M \) is the total number of the triangular cells contained in one Kagome sub-structure cell wall. Then, the relationship between \( M \), \( N \) and \( n \) are expressed as:

\[
\begin{align*}
N = 1: & \quad M = 2[(n-1)-0] \\
N = 2: & \quad M = 2[2(n-1)-2] \\
N = 3: & \quad M = 2[3(n-1)-2-4]
\end{align*}
\]  

Then, by inductive method, we find:

\[
M = 2[N(n-1)-C_n] \quad 1 \leq N \leq \frac{n}{2}
\]  

with

\[
C_n = N(N-1)
\]  

(Substituting Eq. (C.3) into Eq. (C.2) gives:

\[
M = 2N(n-N) \quad (1 \leq N \leq \frac{n}{2})
\]

Figure 2

![Graph showing the relationship between $v_e$ and $\phi$.]
Figure 6

Graph showing the relationship between $\sigma_M / \sigma_0$ and $N$ for different values of $t_0/l_0$. The graph includes markers for $t_0/l_0 = 0.01$, $0.05$, $0.1$, $0.2$, and $0.3$ with corresponding line styles.
Figure 7

\[ \lambda = 1/50 \]

![Graph showing the relationship between \( t_0/l_0 \) and \( E_M/E_0 \)]
Figure 9
Figure 15
Figure 16

\[ \lambda = 1/20 \]

The graph shows the relationship between \( \frac{k_M}{k_O} \) and \( N \) for different values of \( \frac{l_0}{l_0} \):
- \( \frac{l_0}{l_0} = 0.01 \) (blue line)
- \( \frac{l_0}{l_0} = 0.05 \) (red line)
- \( \frac{l_0}{l_0} = 0.1 \) (green line)
- \( \frac{l_0}{l_0} = 0.2 \) (purple line)
- \( \frac{l_0}{l_0} = 0.3 \) (black line)
Figure 18

\[ t_0/l_0 = 0.1, \lambda = 1/20 \]

The graph shows the relationship between \( N \) and \( E_M/E_0 \) for different sub-structures.

- **Hexagonal sub-structure** (blue line)
- **Triangular sub-structure** (red line)
- **Kagome sub-structure** (green line)
Figure 19

\[
t_0/l_0 = 0.3, \lambda = 1/20
\]

The graph shows the relationship between the normalized stiffness ratio \( k_M / k_O \) and the number of sub-units \( N \). The data is categorized into three sub-structures: Hexagonal, Triangular, and Kagome. Each sub-structure is represented by a different line color:
- Hexagonal sub-structure: Blue line
- Triangular sub-structure: Red line
- Kagome sub-structure: Green line

The x-axis represents the number of sub-units \( N \), ranging from 2 to 20, and the y-axis represents the normalized stiffness ratio \( k_M / k_O \), ranging from 0.4 to 1.4.
$t_0/l_0 = 0.3$, $\lambda = 1/20$

- Hexagonal sub-structure
- Triangular sub-structure
- Kagome sub-structure
